ABSTRACT

A CS searches in advance for information about unique words used by neighboring CSs to hold the information in a storage unit (70). When an LCH establishment request is made by a PS in the cell of the CS, it is confirmed whether or not there is an empty traffic slot. Further, with reference to the unique word information of the neighboring CSs of the same frequency and the same slot as the empty slot to be allocated, an unused unique word pattern is allocated.
